ES9822 PRO

32-bit High-Performance 2-Channel ADC

Product Datasheet

The SABRE® ES9822 PRO is the world's highest performance 32-bit analog-to-digital (A/D) converter targeted for professional audio applications such as high-quality recording systems, mixer consoles and digital audio workstations (DAW), test equipment, instruments, audio processors, digital turntables, and consumer applications.

The ES9822 PRO has 2 integrated ADCs which use the ESS proprietary Hyperstream® II ADC Architecture, which delivers unprecedented SABRE HiFi® audio sound quality and specifications, including a DNR of +128dB in mono mode and a DNR +125dB, THD+N of -117dB in 2 channel mode.

The SABRE® ADC supports synchronous S/PDIF, I²S master/slave, or native DSD output. For the most demanding audio enthusiast, the ES9822 PRO supports RAW data output, allowing the user to apply their own custom handling of the data.

The ES9822 PRO comes in a small compact package and consumes less than 170mW.

The ES9822 PRO can use pre-programed filter coefficients to match perfectly with the SABRE® PRO Series of DACs including the ES9038PRO. These complimentary filters allow for analog-digital-analog processing with the upmost audio fidelity and minimized time-domain smearing.

The Audio Signal Processor (ASP) integrated in the ADC allows for custom filtering such as RIAA presets to be implemented in the ADC, eliminating the need for re-processing later in the signal path.

The ES9822 PRO has an Ultra-Low Noise Floor Bandwidth of 200kHz. This bandwidth is up to 10 times wider than the competition, enabling higher resolution at higher sample rates.

Interface Modes

The ES9822 PRO registers can be accessed either using an I²C or SPI interface.

The MODE pin (Pin 3) determines which interface will be used.

I²C Slave/Synchronous Slave Interface Commands

The I²C Slave/Synchronous Slave interface is used when the MODE pin (Pin 3) is pulled low.
The I²C interface can be accessed using Pin 25, 26, 27 and 28.

- Pin 25 SDA
- Pin 26 SCL
- Pin 27 ADDR1
- Pin 28 ADDR2

The ADDR1 (Pin 27) and ADDR2 (Pin 28) pins determine the I²C address.
The R/W bit determines the command type, Read (1) or Write (0).

- I²C Slave Address = [5'b01000, ADDR2, ADDR1, R/W]
- I²C Synchronous Slave Address = [5'b01001, ADDR2, ADDR1, R/W]

Note: The I²C Slave interface requires an MCLK present to function, the I²C Synchronous Slave interface does not.

RAW Format

The ES9822 PRO can output the RAW data of the ADC to GPIOs 1-8. The channel output from the RAW GPIOs is determined by the INPUT_DATA_MAPPING_CHx registers. The RAW data outputs are a single data rate (SDR) of remapped CH1, and by setting RAW_DATA_DDR the RAW data outputs become double data rate (DDR), with the mapped CH1 on the falling edge, and the mapped CH2 on the rising edge of the RAW data clock on GPIO1.

The RAW clock rate on GPIO1 is required to be 22.5792MHz (512 x 44.1kHz sample rate) / 24.576MHz (512 x 48kHz) respectively by setting RAW_DATA_CLK_DIV2 when using a 45.1584/49.152MHz SYS_CLK.

Digital Signal Path

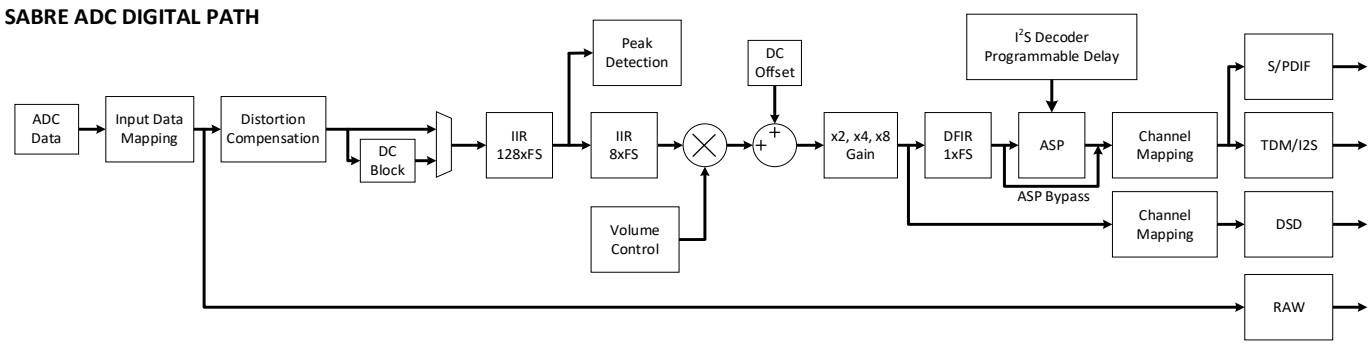

Figure 14 - Digital Signal Path

Input Data Mapping

The ES9822 PRO features input data mapping which can be configured to send any incoming ADC data to either of the 2 channels into the digital signal path.

Input Data Mapping Register

- Register 17[3:2] INPUT_DATA_MAPPING_CH2
- Register 17[1:0] INPUT_DATA_MAPPING_CH1

Distortion Compensation[1]

Distortion Compensation minimizes the non-linearities of the analog to digital data path. The ES9822 PRO can help compensate for system second and third harmonic distortion. For optimal results, compensation coefficients should be tuned for each device and channel.

Distortion Compensation Enable Registers

- Register 102: ADC CH1 THD COMP CONFIG
- Register 119: ADC CH2 THD COMP CONFIG

DC Block

The integrated DC block exhibits a high cutoff frequency (-3dB @ 30Hz).

It is recommended to use the ASP to implement customizable DC blocking filters with lower cutoff frequencies. Ask your local FAE or Distributor for the DC Blocking Filter ASP Application Note.

[1] For more information on using Distortion Compensation, please reference the Distortion Compensation Application Note. Available from your local FAE Upon request

Peak Detection[1]

If the peak level of the ES9822 PRO device's input audio stream rises above the programmed ADCx_PEAK_LEVEL value, the corresponding peak flag will be set. The level will decay at a rate based off the value of ADCx_PEAK_DECAY_RATE. The peak detection can be toggled on or off using the ADCx_ENABLE_PEAK_DETECT registers. The peak flag will stay set until it is cleared with INTERRUPT_CLEAR_CHx_PEAK_DETECTION. Any of the GPIO pins can be configured to output the state of any of the peak flags if INTERRUPT_MASK_CHx_PEAK_ DETECTION is set for the corresponding channel.

Peak Level Registers:

- Register 106: ADC CH1 PEAK DETECTOR LEVEL
- Register 123: ADC CH2 PEAK DETECTOR LEVEL

Peak Decay Rate Register

- Register 105[6:2]: ADC1_PEAK_DECAY_RATE
- Register 122[6:2]: ADC2_PEAK_DECAY_RATE

$$N(t) = N_0 exp\left(\frac{-FS * t}{2^{decay\_rate}}\right)$$

$$N(t) = N_0 - \frac{20 * FS * t}{ln(10) * 2^{decay\_rate}}[dB]$$

$$\frac{dN}{dt} = -\frac{N * FS}{2^{decay\_rate}}[1/s]$$

Peak Enable Register

- Register 105[0]: ADC1_ENABLE_PEAK_DETECT
- Register 122[0]: ADC2_ENABLE_PEAK_DETECT

Peak Interrupt Clear Registers:

- Register 27[5:4]: INTERRUPT_CLEAR_CHx_PEAK_DETECTION

Peak Interrupt Mask Registers

- Register 27[1:0]: INTERRUPT_MASK_CHx_PEAK_DETECTION

The GPIO READBACK register values 4'd4 and 4'd5 output the peak interrupt state for CH1 and CH2, respectively. The corresponding channel bit in Register 27[1:0] INTERRUPT_CLEAR_CHx_PEAK_DETECTION needs to be set for the GPIO to output the flag value.

[1] For further information on using Peak Detection, please reference the Peak Detector Configuration Application Note. Available from your local FAE upon request.

Volume Control

This volume control is intended for use during audio playback. Each channel can be digitally attenuated from 0dB to –84dB in 0.5dB steps. The attenuation circuit automatically uses micro-stepping between 0.5dB register settings so that no switching noise occurs during the volume control transition. When a new volume level is set, the attenuation circuit will ramp softly to the new level. Each 0.5dB step takes up to 64 intermediate steps depending on the ADC CHx VOLUME RATE setting.

Volume Level Configuration Registers:

- Register 109-110: ADC CH1 VOLUME
- Register 126-127: ADC CH2 VOLUME

Volume Rate Configuration Registers:

- Register 111: ADC CH1 VOLUME RATE
- Register 128: ADC CH2 VOLUME RATE

DC Offset

The ES9822 PRO has a built in DC offset that can be used to add per channel DC offset. To achieve this, the 16-bit signed register must be set to either have a positive or negative offset. To achieve a positive DC offset, the register must be within the range of 16'h0001(-120dB) to 16'h7FFF(-30dB). To achieve a negative DC offset, the register must be within the range of 16'h8000(-30dB) to 16'hFFFF(-120dB).

The offset is set by using the following equation:

$$Offset[dB] = 20log_{10}\left(\frac{ADCx\_DC\_OFFSET}{(2^{15}-1)*2^{5}}\right)$$

DC Offset Registers

- Register 107-108: ADC1_DC_OFFSET
- Register 124-125: ADC2_DC_OFFSET

Digital Gain

The ES9822 PRO has an additional digital gain that can be added through registers. Settings for +6dB (~2x), +12dB (~4x) or +18dB (~8x) gain are available for each ADC channel.

Digital Gain Registers:

- Register 112[1:0]: ADC1_DATA_GAIN
- Register 129[1:0]: ADC2_DATA_GAIN

Digital Filters

The ES9822 PRO has 8 pre-programmed digital filters. See Pre-Programmed Digital Filters for more information.

Audio signal Processor (ASP)[1]

The ES9822 PRO includes 2 stereo audio signal processors (ASP) which can be used to implement both custom filter coefficients as well as custom filter architectures. See Digital Signal Path diagram for location in the data path.

The ASP can be used to implement a DC blocking high pass, parametric equalizer (PEQ), and/or a RIAA filter.

ESS recommends using the ASP for DC Blocking function. See DC Blocking Filter Application note, available from your local FAE or Distributor upon request.

TDM Cascade Mode

The ES9822 PRO features TDM cascade mode. Cascade mode allows the digital output from one chip to be input (through GPIO4) to the next, and the last chip on the chain outputting the final data on serial data line. To enable TDM Cascade mode, set TDM_CASCADE to 1, and configure GPIO4 as input and GPIO3 as output. The figure below shows how several ES9822 PRO can be combined in TDM cascade mode.

Note: Cascade mode is for a minimum of an 8 channel TDM data line (TDM_CH_NUM ≥ 7).

Note: To ensure optimal performance, after setup of TDM Cascade Mode, the respective I²S or LJ Resync script must be written to all ES9822 PROs in Slave mode. See Resync for the respective script.

TDM / PCM Parallel Mode

The ES9822 PRO also supports TDM / PCM in parallel mode. In this case, the ES9822 PROs will simply connect the output data lines together. Each ES9822 PRO will output data during the designated slots during a single frame of the TDM / PCM data line, then switch to high impedance so that the next chip may output its data onto the TDM data line. To set up TDM parallel mode, no specific registers are required.

Note: Parallel mode supports TDM and I²S (TDM_CH_NUM ≥ 1).

Note: To ensure optimal performance, after setup of TDM Parallel Mode, the respective I²S or LJ Resync script must be written to all ES9822 PROs in Slave mode. See Addendum for the script.

Pre-Programmed Digital Filters

The ES9822 PRO has 8 pre-programmed digital filters. The latency for each filter reduces (scales) with increasing sample rates. (See Register 113[4:2] FILTER_SHAPE for configuration)

#	Filter	Description
1	Minimum Phase (default)	Version 2 of minimum phase fast roll-off (#6) with less ripple and more image rejection
2	Linear Phase Apodizing Fast Roll-Off	Full image rejection by FS/2 to avoid any aliasing, with smooth roll-off starting before 20k.
3	Linear Phase Fast Roll-Off	Sabre legacy filter, optimized for image rejection @ 0.55FS
4	Linear Phase Fast Roll-Off Low-Ripple	Sabre legacy filter, optimized for in-band ripple
5	Linear Phase Slow Roll-Off	Sabre legacy filter, optimized for lower latency, but symmetric impulse response
6	Minimum Phase Fast Roll-Off	Low latency, minimal pre ringing and low passband ripple, image rejection @ 0.55FS
7	Minimum Phase Slow Roll-Off	Lowest latency at the cost of image rejection
8	Minimum Phase Fast Roll-Off Low Dispersion	Provides a nice balance of the low latency of minimum phase filters and the low dispersion of linear phase filters. Minimal pre-ringing is added to achieve the low dispersion in the audio band.

Table 11 - Pre-Programmed Digital Filter Descriptions

Note: Minimum phase filters are asymmetric filters that work to minimize the pre-echo of the filter, while still maintaining an excellent frequency response and they peak earlier than linear phase filters, resulting in a lower group delay. Minimum phase filters usually feature zero cycles of pre-echo, which can result in improved audio quality.

PCM Filter Latency

The following table shows the simulated latency of each filter at 44.1kHz sampling rate. Measurements were taken from the external impulse response prior to being down sampled to 1FS. The extra sample delay to get the data encoded accounts for external processing time to serialize the data stream. Latency delay will reduce (scale) with sampling rate.

64FS Mode

When the MCLK/FS ratio is required to be 64, it is necessary for the ES9822 PRO to be running in 64FS Mode. 64FS Mode can be entered by setting:

Software Register

- Register 0[3] ENABLE_64FS_MODE = 1'b1
    - Use for 64FS ratios, including 705.6/768kHz sample rates.

This mode enables the Minimum Phase 64FS filter. See filter properties below.

Minimum Phase 64FS Mode Latency

The following table shows the simulated latency at 705.6kHz sampling rate and is very similar at 768kHz. Measurements were taken from the external impulse response prior to being down sampled to 1FS. The extra sample delay to get the data encoded accounts for external processing time to serialize the data stream. Latency delay will reduce (scale) with sampling rate.

The ES9822 PRO includes features for selection and manipulating the input clock source.

The minimum MCLK frequency is 22.579MHz.

When using 24.576MHz or 22.579MHz, it is preferable to use GPIO4-6 as the data output.

- Register 74-91 (GPIOx/x_CONFIG) - Set desired GPIO as AUX output and enable output mode.
- Register 12-13[6:5] (TDM_LINE_SEL_CHx) - Change TDM Line Select to desired GPIO.

Master Clock (MCLK) and Bit-Clock (BCK) Timing

The ES9822 PRO has a phase relationship requirement between MCLK (System Clock) and BCK (Bit Clock). The internal ADC_CLK (which must be 24.576/22.5792MHz) is derived from the provided MCLK. In slave mode, the ES9822 PRO requires the BCK transition to be within a specific range of the MCLK period. This is due to the synchronization circuitry that aligns the output samples with the input clocks. The table below specifies the amount of time required between the bit clock transition and the MCLK falling edge. To achieve this, follow the MCLK to BCK timing outlined below.

45/49MHz MCLK

Register Overview

I²C Slave Interface (Device Address 0x40, 0x42, 0x44, 0x46)

This interface contains Read/Write and Read-only registers. A system clock must be enabled through the write-only registers to read/write these registers.

Multi-byte registers must be written from LSB to MSB. Data is latched when MSB is written.
Multi-byte registers must be read from LSB to MSB. Data is latched when LSB is read.
MSB is always stored in the highest register address.

Read/Write Register Addresses

Registers 0–179 (0x00 – 0xB3) are read/write registers.

Read-only Register Addresses

Registers 224 – 253 (0xE0 – 0xFD) are read only registers.

I²C Synchronous Slave Interface (Device Address 0x48, 0x4A, 0x4C, 0x4E)

This interface contains Write-only registers. These registers can be written even when there is no system clock present. These registers must be written to enable read and write access to the rest of the registers.

When the device is inactive, all peripherals are automatically disabled, and all clocks are stopped. An interrupt or a reset can wake the ES9822 PRO.

Write-only Register Addresses

Registers 192-194 (0xC0 - 0xC2) are write only registers.

Multi-Byte Registers

Multi-byte registers must be written from LSB to MSB. Data is latched when MSB is written.

MSB is always stored in the highest register address.

Reflow Process Considerations

Temperature Controlled

For lead-free soldering, the characterization and optimization of the reflow process is the most important factor to consider.

The lead-free alloy solder has a melting point of 217°C. This alloy requires a minimum reflow temperature of 235°C to ensure good wetting. The maximum reflow temperature is in the 245°C to 260°C range, depending on the package size (RPC-2 Pb-Free Process – Classification Temperatures (Tc)). This narrows the process window for lead-free soldering to 10°C to 20°C.

The increase in peak reflow temperature in combination with the narrow process window makes the development of an optimal reflow profile a critical factor for ensuring a successful lead-free assembly process. The major factors contributing to the development of an optimal thermal profile are the size and weight of the assembly, the density of the components, the mix of large and small components, and the paste chemistry being used.

Reflow profiling needs to be performed by attaching calibrated thermocouples well adhered to the device as well as other critical locations on the board to ensure that all components are heated to temperatures above the minimum reflow temperatures and that smaller components do not exceed the maximum temperature limits (Table RPC-2).

To ensure that all packages can be successfully and reliably assembled, the reflow profiles studied and recommended by ESS are based on the JEDEC/IPC standard J-STD-020 revision D.1.

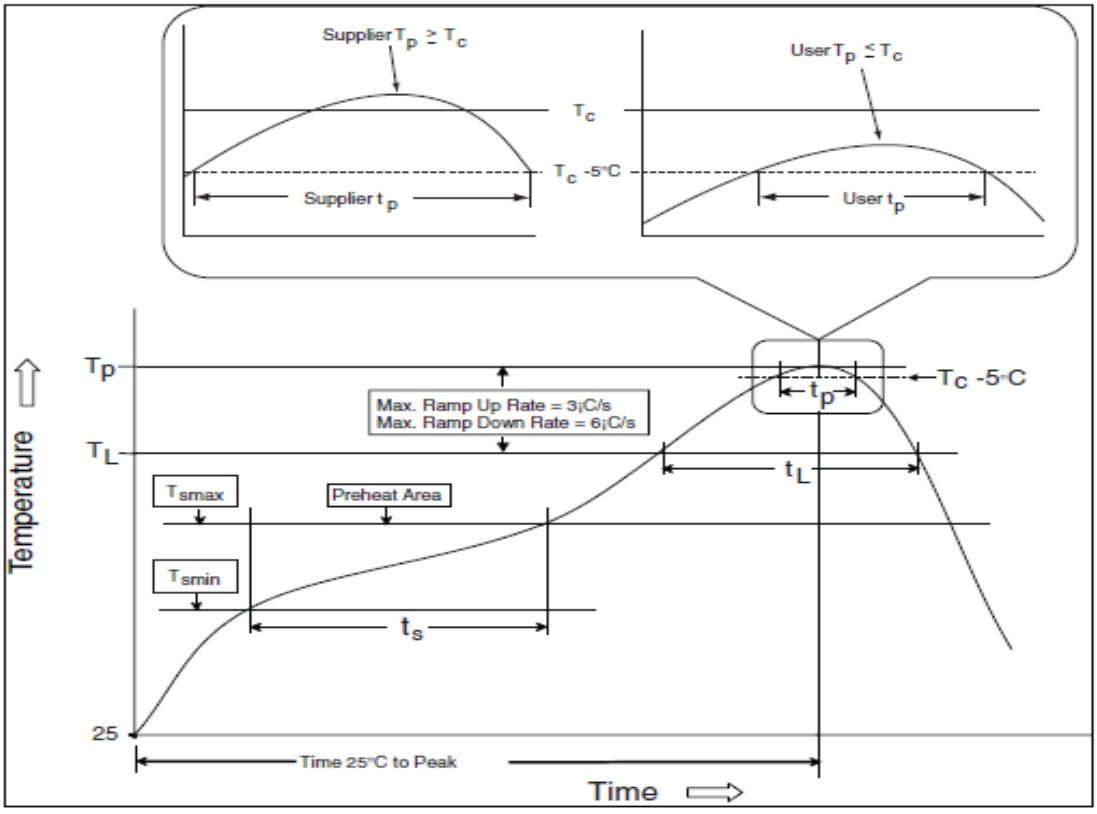

Figure 33 - IR/Convection Reflow Profile (IPC/JEDEC J-STD-020D.1)

Reflow is allowed 3 times. Caution must be taken to ensure time between re-flow runs does not exceed the allowed time by the moisture sensitivity label. If the time elapsed between the re-flows exceeds the moisture sensitivity time bake the board according to the moisture sensitivity label instructions.

Manual

Allowed up to 2 times with maximum temperature of 350°C no longer than 3 seconds.

RPC-1 Classification Reflow Profile

Profile Feature	Pb-Free Assembly
Preheat/Soak Temperature Min (Tsmin) Temperature Max (Tsmax) Time (ts) from (Tsmin to Tsmax)	 150°C 200°C 60-120 seconds
Ramp-up rate (TL to Tp)	3°C / second maximum
Liquidous temperature (TL) Time (tL) maintained above TL	217°C 60-150 seconds
Peak package body temperature (Tp)	For users Tp must not exceed the classification temp in Table RPC-2. For suppliers Tp must equal or exceed the Classification temp in Table RPC-2.
Time (tp)* within 5°C of the specified classification temperature (Tc), see IR/Convection Reflow Profile Figure	30* seconds
Ramp-down rate (Tp to TL)	6°C / second maximum
Time 25°C to peak temperature	8 minutes maximum
* Tolerance for peak profile temperature (Tp) is defined as a supplier minimum and a user maximum.	

Table 36 - RPC-1 Classification Reflow Profile

All temperatures refer to the center of the package, measured on the package body surface that is facing up during assembly reflow (e.g., live-bug). If parts are reflowed in other than the normal live-bug assembly reflow orientation (i.e., dead-bug), Tp shall be within ±2°C of the live-bug Tp and still meet the Tc requirements, otherwise, the profile shall be adjusted to achieve the latter. To accurately measure actual peak package body temperatures, refer to JEP140 for recommended thermocouple use.

Reflow profiles in this document are for classification/preconditioning and are not meant to specify board assembly profiles. Actual board assembly profiles should be developed based on specific process needs and board designs and should not exceed the parameters in Table RPC-1.

For example, if Tc is 260°C and time tp is 30 seconds, this means the following for the supplier and the user.

For a supplier: The peak temperature must be at least 260°C. The time above 255°C must be at least 30 seconds.

For a user: The peak temperature must not exceed 260°C. The time above 255°C must not exceed 30 seconds.

All components in the test load shall meet the classification profile requirements.

RPC-2 Pb-Free Process – Classification Temperatures (Tc)

Package Thickness	Volume mm3, <350	Volume mm3, 350 to 2000	Volume mm3, >2000
<1.6 mm	260°C	260°C	260°C
1.6 mm – 2.5 mm	260°C	250°C	245°C
>2.5 mm	250°C	245°C	245°C

Table 37 - RPC-2 Pb-Free Process

At the discretion of the device manufacturer, but not the board assembler/user, the maximum peak package body temperature (Tp) can exceed the values specified in Table RPC-2. The use of a higher Tp does not change the classification temperature (Tc).

Package volume excludes external terminals (e.g., balls, bumps, lands, leads) and/or nonintegral heat sinks.

The maximum component temperature reached during reflow depends on package thickness and volume. The use of convection reflow processes reduces the thermal gradients between packages. However, thermal gradients due to differences in thermal mass of SMD packages may still exist.

Resync

The respective s2m script is to be run on all slave mode ES9822 PROs in TDM Cascade or Parallel mode after clocks from the master have been initialized. This is to ensure all chips are properly synced with each other for optimal performance.

I²S Resync

```
w 34 0x1D; // Turn off AUTO_FIR_SYNC
w 33 0x35; // FORCE_FIR_SYNC = 1'b1
w 33 0x15; // FORCE_FIR_SYNC = 1'b0
w 34 0x1F; // Turn on AUTO_FIR_SYNC
```

LJ Resync

```
w 34 0x1D; // Turn off AUTO_FIR_SYNC
w 33 0x35; // FORCE_FIR_SYNC = 1'b1
w 33 0x95; // FORCE_FIR_SYNC = 1'b0
w 34 0x1F; // Turn on AUTO_FIR_SYNC
